Facilitating and Rewarding Creativity during New Product Development

Abstract

In an effort to improve creativity in the new product development process, many firms offer incentive programs, creativity training programs, or both. Yet creativity continues to be a construct that is not well understood in marketing, and little research has examined the joint influence of such initiatives on creative outcomes. As a result there is considerable variance in the way firms approach these issues. In a qualitative study of twenty firms, it was found that fifteen offered some type of incentive program while only seven engaged in creativity training (a subset used both). Given that prior research has consistently found that extrinsic rewards offered in isolation actually undermine the creative process (by reducing intrinsic motivation) it appears many firms may be unwittingly hampering their own creative efforts. However, two experiments demonstrated that the effect of rewards can be made positive if offered in conjunction with appropriate training. Specifically, product creativity was highest when the monetary reward was paired with a dedicated creative training technique. The training alters the influence of the reward such that it reinforces (rather than undermines) intrinsic motivation. Managers can improve the effectiveness of their creative efforts by leveraging the use of incentives and training in combination.

Keywords: Creativity, Creativity Training, Extrinsic Rewards, Intrinsic Motivation, New Product Development.
“Creativity has always been prized in American society, but it’s never really been understood. While our creativity scores decline unchecked, the current national strategy for creativity consists of little more than praying for a Greek muse to drop by our houses. The problems we face now, and in the future, simply demand that we do more than just hope for inspiration to strike” (p. 49).

Bronson & Merryman (7/10/2010), Newsweek cover story: “Creativity in America: The Creativity Crisis”

Corporations have a vested interest in promoting creativity among their employees and stakeholders. The success of new product development (NPD) efforts, for example, depends to a great extent on the creativity of the ideas underlying them (Scanlon and Jana 2007). In a recent IBM poll of 1500 CEOs, creativity even edged out integrity as the most important leadership quality for business success (Carr 2010). While creativity’s importance is broadly acknowledged by business leaders, the methods for achieving creative thought remain elusive.

Creativity is commonly defined as the production of something that is both original and useful (Amabile 1996; Bronson and Merryman 2010; Runco 1997; Smith, Ward, and Finke 1995; Sternberg 1999). For example, a creative new product would be one that differs from existing products in a novel way, but is still effective (or even more effective) in accomplishing the purpose for which it was intended. While this definition of creativity is widely accepted, Hauser, Tellis, and Griffin (2006) argue that marketing academics must do much more to provide insights that help firms achieve their creative aims. In their influential review of innovation in marketing, Hauser and colleagues named creativity in the “fuzzy front end” of NPD as a critical research priority. Specifically, they called for more research on such issues as how to structure
incentives to motivate employees to be more creative and how to develop tools to facilitate creativity.

Our research directly addresses these issues by first examining firms’ actual approaches to encouraging and rewarding creative thought. In this initial qualitative study, we interview senior executives at a total of 20 firms to understand the role of creativity in their organizations and how it is fostered. Two experiments are then used to test the effectiveness of two key managerial tools, rewards and creativity training, in enhancing an individual’s creative performance. These studies find that it is the interaction of these two variables that matters when it comes to producing creative product outcomes. Namely, we find that creativity training alters the reward influence such that it turns a normally neutral or negative effect into a positive one. While prior work has examined the influence of extrinsic rewards and the influence of creativity training independently, little research has considered their joint influence. This is an important oversight given the prevalence of both training and incentive programs in industry.

Together, our studies contribute to the marketing literature in two ways. Managerially, our qualitative study establishes the variance in approaches and beliefs that firms have when it comes to encouraging creative thought. Our experiments then demonstrate how rewards and creativity training, both of which are easily implemented, may enhance the creative thinking of those engaged in the fuzzy-front-end of new product development.

Theoretically, our experimental results introduce an important moderating factor in the relationship between rewards and creative product outcomes. The effect of extrinsic incentives (e.g., rewards) on creativity has been a point of longstanding debate within both marketing and psychology (see e.g. Lepper, Green, and Nisbett 1973; Cameron and Pierce 1994; Deci, Koestner, and Ryan 1999a,b; Eisenberger, Pierce, and Cameron 1999; Eisenberger and Shanock
2003; Lepper, Keavney, and Drake 1996; Ryan and Deci 1996). The majority of these studies find that rewards undermine the creative process by diminishing intrinsic motivation (i.e., the motivation to engage in an activity for its own sake; see Csikszentmihalyi and Getzels 1973; Collins and Amabile 1999; Deci, Koestner, and Ryan 1999a; Ryan and Deci 2000).

A few empirical studies using schoolchildren, however, do find that rewards can enhance creativity when they are accompanied by some form of creativity training (e.g. Eisenberger, Armeli and Pretz 1998; Eisenberger and Selbst 1994). The training cues children that creativity is expected (and rewarded) by others (e.g. teachers, parents), and therefore they exert greater effort in this direction. Our findings are novel, however, because they demonstrate that rewards, when accompanied by appropriate training, can enhance (not diminish) intrinsic motivation, which in turn facilitates creative outcomes. Intrinsic motivation is particularly important in complex and effortful creativity tasks like new product development.

**Study 1**

The goal of this study was to better understand managers’ strategies for obtaining and rewarding creative thought in their organizations. Respondents were recruited using a snowball technique where we began with our own university contacts and then relied on informants to identify additional individuals who would be particularly knowledgeable about this topic. This technique produced a total of 20 interviews with a variety of marketing and NPD executives (see Table 1 for company and contact profiles). Our sample was diverse, including firms with annual revenues ranging from $25 million to $79 billion, in industries ranging from chemicals to natural foods, and in countries in North America, Europe, and Asia. Interviews lasted from 25 to 75
minutes, with an average duration of 40 minutes. Each interview was recorded and transcribed (with the exception of two informants who declined to be recorded).

--- Insert Table 1 about here ----- 

The interviews followed a semi-structured format in which an initial set of prepared questions were used to guide the interview, supplemented with specific follow-up questions that were based on each informant’s individual responses. This approach is drawn from grounded theory and was selected because, of the major qualitative techniques, it is among the most amenable to mixed-method research (Creswell 2009; Corbin and Strauss 2008). It has also been employed successfully in numerous past marketing studies (see e.g., Dahl and Moreau 2007; Fournier and Mick 1999; Flint, Woodruff, and Gardial 2002; Keaveney 1995; Noble and Mokwa 1999). The three general questions that guided the interviews were: 1) In what areas or functions within your company is creativity deemed important and valuable?; 2) What structures or programs are in place to encourage creative thinking among your employees?; 3) Do you use any type of incentive programs to try and enhance the creativity of your employees?

The first of the three questions yielded relatively consistent results across the diverse set of firms. Seventeen of the 20 respondents mentioned product innovation and new product development as the areas in which creativity was most critical to their organization. Eleven of the respondents also mentioned that marketing benefited greatly from creative thought. Internal processes and operations were mentioned as key areas by six respondents, and one interviewee mentioned that creativity had been critical in the cost-cutting initiatives taken by his firm. The second two questions, however, yielded significantly more variance across the firms, and responses to each of those questions are described in greater detail below.
How Firms Obtain Creative Insights

As Table 2 highlights, the firms in our sample used a wide variety of methods to obtain creative insights. A number of these firms outsource many of their creative tasks, relying on outside consultants to assist them in their creative endeavors. Notably, this practice is used much more heavily by the larger firms in our sample (firms are numbered in reverse order of size). When asked why they outsource their creative activities, one respondent explained that it is because, “It’s difficult, and there are people over time who build a great amount of expertise in the innovation area.” That said, one large firm we spoke with said that they started out relying heavily on consultants but decided that creativity and innovation were too critical to completely outsource. Thus, they now rely on a balanced model where consulting firms are utilized to enhance their own internal innovation efforts.

---- Insert Table 2 about here -----

Two firms reported that they either do their own internal creativity training (e.g., TRIZ) or encourage their employees to follow their proprietary approach to creativity (e.g., Converter; see Table 2). Five of the firms reported using informal brainstorming sessions on an ad-hoc basis, while six firms did not do anything to try and enhance the creativity of their employees. A respondent from one of the larger firms in this “no strategy” category explained that, “You can’t teach creativity.” Interestingly, this belief stands in direct contrast to a great deal of prior research noting just the opposite (see, e.g., Carr 2010; Scott, Leritz, and Mumford 2004a for a review and meta-analysis).

How Firms Incent and Reward Creative Insights
We observed similar variance in how the firms in our sample approach and use extrinsic incentives for rewarding creativity (see Table 3). Seven of our respondents, across firm size and industry, reported using some type of public recognition to identify and appreciate employees’ and/or team contributions of creative ideas. Most of these rewards were described as non-financial (e.g., a plaque presented in a public forum such as an annual banquet). In a similar fashion, five other firms reported using prizes as recognition for employees’ or teams’ creative accomplishments. These prizes tended to be small. One respondent described receiving “cheesy,” retailer gift cards given for the “wackiest” ideas in a new product ideation session. However, in another firm the prize was much more substantial: a trip to Paris for the development team, awarded in conjunction with the launch of a promising new product.

Some firms utilized rewards with even more significant repercussions. At four firms in our sample, innovation and creativity were formal expectations of certain employees. The annual merit raises for these individuals depended, in part, on their performance in these areas. Three firms also used financial bonuses to reward a team’s creative accomplishments, and two reported using bonuses to reward individual achievements. In one case, the reward approached $10,000 (for securing a patent). Interestingly, five of the firms in our sample reported using no extrinsic rewards at all. As one respondent explained, “Creativity is in the culture and it’s just expected.”

Innovation Consultants

One of the more interesting findings to emerge from these interviews was the large firms’ reliance on outsourcing their creative efforts. While this decision to outsource is consistent with the increased specialization characteristic of these large firms, it is also surprising given their
significant access to vast internal resources. Thus, to better understand how these innovation consultants develop and contribute creative ideas, we sought out principals at three respected innovation consulting firms that, according to one of the CEOs, “teach people to fish.” All three of these firms made heavy use of creativity training. As summed up by the president of one firm:

“Creativity is 94% process and system; it’s 6% employee. Most firms get it exactly backwards.”

Not surprisingly, all three consulting firms were very systematic in their approach to creativity. One firm trains its people in analogical thinking and visualization to improve ideation results. The second firm trains people to structure their ideation sessions into three levels of opportunities from which they start the ideation process. The third firm recognizes the value that constraints play in the creative process. To them, the key is combining discipline and processes to achieve creativity. Consultants either work with the firms’ employees during ideation sessions or they actually do the creative development themselves with guidance from the firm.

When it comes to advising firms on the use of incentive and rewards systems, however, the consultants did not have a great deal to offer. Two of the three respondents did not comment specifically on the role of extrinsic rewards. The third respondent came down solidly against them: “Just take away the extrinsic incentives.”

Discussion

Overall, our findings from this qualitative study are consistent with research showing that firms overwhelmingly recognize the importance of creative thought in innovation and new product development (see Scanlon and Jana 2007). However, our results also show surprisingly little consistency across firms when it comes to obtaining and rewarding creative insights from their employees. Firms follow a variety of approaches for facilitating and rewarding creativity,
and our findings revealed relatively extreme perspectives on whether or not creativity could be taught. However, when one considers the historical challenges involved in teaching creativity, and the equivocal results reported in the academic literature, these extreme attitudes appear less surprising.

While some firms believed in combining creativity training (e.g., TRIZ) with substantial extrinsic rewards (e.g., $10,000 for a patent filing), others believed that creativity could not be taught and/or that rewards were detrimental to their creative efforts. Thus, to provide more clarity on the relationship between extrinsic rewards and different types of creativity training, we employ an experimental approach using creative tasks that closely approximate the types of challenges firms face in the early stages (e.g., the “fuzzy front end”) of their new product development processes. In the following sections, we first review the literature on extrinsic rewards, training, and creativity and then describe our tests of the theories.

**Extrinsic Rewards and Creativity**

A considerable body of evidence now suggests that rewards undermine creativity (cf. Amabile 1996; Deci, Koestner, and Ryan 1999a). Rewards are believed to erode creativity by reducing intrinsic motivation (i.e. a person’s inherent interest in the task or activity for its own sake). Intrinsically motivated individuals are often described as becoming absorbed in a task, and deriving enjoyment from the challenge it provides. Conversely, individuals experiencing low intrinsic interest find an activity to be tedious and boring. Because creativity is mentally taxing and often requires sustained effort, intrinsic motivation is considered critical to this process (see e.g., Amabile 1996).
How do rewards diminish intrinsic motivation for creative tasks? The provision of a reward is believed to cause an interpretive shift in the individual’s reason for engaging in the activity. Effort shifts from being put forth out of sheer interest to being supplied strictly as a trade for compensation (Amabile 1996). Essentially the provision of the reward causes the task to be, “defined more narrowly (simply as a means to an extrinsic end, rather than as an opportunity for exploration and cognitive play)” (Amabile and Cheek 1988, 60). Again, because creativity usually requires sustained effort, this loss of intrinsic motivation is believed to more than offset whatever benefits the reward otherwise provides. Some of the earliest evidence of this effect came from the field of education, where educators found their attempts to re-channel children’s natural curiosity into academic exercises (replete with grades, stars, etc.) resulted in a sharp loss of interest (Lepper, Greene, and Nisbett 1973).

However, people do work for compensation, even in creative fields. Thus, researchers began to wonder whether extrinsic rewards must always undermine creativity. One of the first programs to challenge this premise were the “immunization studies” conducted by Hennessey and colleagues (Hennessey, Amabile and Martinage 1989; Hennessey and Zbikowski 1993). These researchers speculated that individuals might be buffered against the de-motivating effects of rewards depending on their interpretation of the role of the reward in the creative process. They reasoned that a reward could either be interpreted as constraining (i.e. as an attempt to exert external control) or as informational (i.e. providing useful information). If perceived as informational, the reward could contribute to positive affect and intrinsic motivation (Hennessey, Amabile, and Martinage 1989).

To test their premise, Hennessey and colleagues showed some students a videotape emphasizing the intrinsic aspects of performing well in school (e.g. how enjoyable it is to learn
something new, the sense of accomplishment one feels from working hard, etc.). Students in a control condition were shown no such video. Similarly, some students were offered an extrinsic reward as part of the study while others were offered no such reward. Students were then asked to compose a brief story that was later evaluated for creativity. Consistent with their prediction, students who were shown the video and offered a reward exhibited higher levels of creativity than students that had only been exposed to one condition or the other.

However, when Hennessey and company attempted a more comprehensive replication of the original findings, they were unable to reverse the negative influence of extrinsic rewards, only to neutralize it (Hennessey and Zbikowski 1993). Given there is a big difference between something that is beneficial versus something that is merely benign, they cautioned that researchers not to be “too quick to abandon our original notions” of the negative influence of extrinsic rewards on creativity, and to seek out new moderators of this relationship (304). We propose that creativity training is one such moderator.

**Creativity Training**

A substantial body of creativity research has focused on whether it is possible to train ordinary individuals to be more creative (e.g., Basadur, Graen and Green 1982; Gordon 1968, Khatena 2000; Osborn 1963; Renzulli 1986). This research (conducted largely outside the business realm) shows that creativity training can make a substantive difference. A meta-analysis by Scott, Leritz, and Mumford (2004a) found an average effect size of .68 for creativity training programs while another study reported an even higher effect size of .77 (Ma 2006). In fact, research has shown that even a single training session can enhance creative abilities and outcomes (Clapham 1997; Dahl, Chattopadhyay, and Gorn 1999). Finally, while early training
programs were hit or miss, as research has uncovered the essential elements of the creative process (e.g., lateral connection, analogical reasoning, divergent and convergent thought), training techniques have become ever more refined (e.g., Baer 1997; Khatena 2000; Parnes 1999).

Though a variety of approaches to creativity training have been developed over the years, two of the most prominent approaches are creative idea production training and creative imagery training (Scott, Leritz and Mumford 2004b). While these two forms vary in terms of their objectives and approach, both make use of different types of visualization and both have been shown to be effective in enhancing creativity (Scott, Leritz, and Mumford 2004b).

**Creative Idea Production Training**

Creative idea production training emphasizes the use of idea generation and elaboration in response to concrete and realistic problems and situations. This approach encourages the person to visualize how someone might experience a problem and new ways in which it can be solved (Finke 1997). Creative idea production training tries to leverage and enhance the mind’s capacity for mental image manipulation (Newell and Simon 1972). An example of this type training in the marketing literature comes from Dahl, Chattopadhyay, and Gorn (1999), who used the technique to induce young engineers to think more empathetically about the challenges the elderly face while driving, particularly when trying to change a flat tire. By seeing a problem and its potential solutions through the eyes of another, engineers who received the training were able to substantially improve upon the design of a traditional car jack, as compared to their untrained counterparts. Creativity inherently involves a certain amount of trial and error, so being able to
mentally manipulate various solutions (without having to actually implement them all) can be of tremendous benefit to creative problem solving (Jay and Perkins 1997; Newall and Simon 1972).

**Creative Imagery Training**

By contrast, creative imagery training is less specific than idea production training. This family of techniques relies heavily on free association with the goal of enhanced lateral thinking (i.e. making connections across distal conceptual planes), and as such tends to be more imaginative in emphasis. For this reason, unrealistic or improbable scenarios are often used to leverage the mind’s capacity for visualization and conceptual manipulation. For example, Khatena’s (2000) “divergent-symbolic” production task (one of the better known creative imagery training techniques) asks participants to imagine a set of inanimate objects contained in a box coming to life. Participants are asked to write out a story about these objects coming together to play. Though this exercise is highly improbable and not problem-specific, it is designed to stimulate imaginative thinking and push conceptual boundaries with the understanding that such thinking may benefit creativity in subsequent unrelated tasks by helping participants break free of fixation (Scott, Leritz, and Mumford 2004b). Imagery training is thus designed to overcome mental blockages and produce moments of insight (Scott, Leritz, and Mumford 2004b).

**The Interaction between Extrinsic Rewards and Creativity Training**

There has been very little research examining how extrinsic rewards influence the effectiveness of creativity training. As noted above, training can positively influence creative outcomes, but why it does so remains an open question. The one marketing study that examined
the relationship between creativity training and product outcomes (Dahl, Chattopadhyay, and Gorn 1999) did not include intrinsic motivation or extrinsic influences on the creative process. Thus, these authors were unable to comment on how training influences intrinsic motivation, or how extrinsic incentives might alter the equation. Does training work because it increases people’s intrinsic task motivation or does it work simply because it helps people work smarter at a creative task?

Training may do both: people may work smarter because they have better skills and they may work harder because they are more intrinsically motivated (i.e., people are more naturally interested in things they believe they are good at). The answer to this question has implications for managers’ strategies for facilitating creative thought. If training at least partly enhances intrinsic motivation, then the provision of a reward could serve to further reinforce task engagement. This would coincide with the reality that people who work in creative fields, do so because they are highly motivated and because they expect to be well compensated for their efforts. Thus, managers who understand how to combine different tools to maximize creative performance stand to enhance their firms’ new product development efforts.

Overall, the lack of research on this interaction is surprising, especially with respect to NPD. The limited research that has examined the joint influence of rewards and training on creativity has occurred in the field of education, and was conducted by Eisenberger and colleagues (e.g., Eisenberger, Armeli, and Pretz 1998; Eisenberger and Selbst 1994). Their research found that incentives could be used to get children to produce more creative drawings, but only if the children were first primed to think of unusual uses for common objects. They suggest that the priming task cues children that creativity is expected and will be rewarded by others such as parents or teachers. While such extrinsic influences may be sufficient to promote
creativity in a children’s drawing task (where the mere choice to make a free drawing instead of copying one was sufficient to be deemed “creative”) there is a question as to whether they would be sufficient to sustain creative effort in more challenging tasks (Deci, Koestner, and Ryan 1999b). Given this, the applicability of these findings to a new product development context is probably limited.

Our view is that training could reverse the otherwise negative or neutralizing influence of rewards on creativity in an NPD task by bolstering intrinsic motivation. Because creativity training emphasizes divergent-thinking, visualization, and exploration, it provides people with two distinct, but important gifts: 1) the cognitive tools to actually work smarter and 2) a feeling of increased competence during the creative task. When people feel more competent, research has shown that their task enjoyment is increased (Dahl and Moreau 2007; Deci, Koestner, and Ryan 1999a). Given this we propose that training may not only give individuals a tool to be more creative, it may also enhance their level of intrinsic motivation. In such instances rewards and training would become mutually reinforcing (not offsetting), as the reward affirms one’s own internal creative efforts. Conversely, for those who do not receive training, a reward is likely to be interpreted as a type of bribe used to induce someone to do something they may otherwise be reluctant to, and, as past research has shown, this is generally not a sustainable way to increase creative effort (Deci, Koestner, and Ryan 1999a).

We test this proposition in two experiments. To enhance the generalizability of our findings, we test our ideas using the two different types of creativity training described above. The first study examines the relationship between creative idea production training and extrinsic rewards while the second study focuses on creative imagery training and those same rewards. To
better understand the mechanism by which the results are achieved, the second study also assesses the role of intrinsic motivation explicitly.

Study 2

Research Design

Two experimental factors (extrinsic rewards and creative idea production training) were manipulated in a 2x2 between-participants design. Participants in the study were 122 undergraduate engineering students at a major mid-western university who were given nominal compensation in exchange for their participation. All participants had also completed their required design course-work at the time of the experiment. A form of creative idea production training (specifically customer-focused visualization) was the creative-thinking skill made accessible in the study (Dahl, Chattopadhyay, and Gorn 1999).

To ensure that no unintended confounding factors influenced task performance, participants completed the study individually. As a further control, one research assistant conducted all 122 sessions over a three-week period. Upon arrival at the session, the participant was randomly assigned to one of the four treatment cells. If the participant had been assigned to one of the creativity training conditions, the research assistant provided it at the beginning of the session. Following the training manipulation (if provided), all participants received a description of the design task. The product design task was the same as that used by Dahl, Chattopadhyay, and Gorn (1999), namely to devise a new car jack for use by seniors (i.e. individuals aged 60 years or older) in order to change a flat tire. The specific description was as follows:

You are asked to develop an innovative and effective car jack design for elderly adults (age 60+). Please produce a thumbnail sketch of your design and include any brief written comments that are necessary to explain your design. Please disregard any
economic, material, or regulatory constraints as you develop your idea. You have up to one hour to complete your design.

For participants in the monetary rewards condition, a description of those rewards then followed (see below). The research assistant next indicated that the participant should first spend some time using scratch paper to sketch out their initial design ideas and then draw their final design on special bond paper. After the participant had completed the design task, s/he was asked to complete a questionnaire containing background measures and a set of manipulation checks.

**Independent Variables**

*Creative idea production training.* Participants who received creative idea production training were provided with the following information:

In solving design problems, many designers find that forming visual images (pictures in the mind) can help them produce innovative and effective designs. One visualization strategy that has been shown to aid in the design process involves visualizing the potential customer of the product. Seeing in your mind, a product-user being involved and interacting with a proposed product design can facilitate the development of design solutions.

After these initial instructions, the designers were given a brief training task (for the full training regimen see the Appendix). The training task used a guided visualization procedure in which participants read a short story about a young adult putting together a television stand. As the participants read the short story they were instructed to stop after reading each sentence in the story and try to picture in their minds the events about which they had just read. The idea was to sequentially break down the assembly process and recognize the specific challenges and problems customers would face at each step.

*Extrinsic rewards.* Participants in the conditions offering extrinsic rewards for the design task received the following information:
Three cash prizes will be awarded to the students producing the first, second and third rated designs ($250, $100, and $50, respectively). Outside judges from the target market for the product will evaluate the designs and the winning designs will be selected from these evaluations.

No such information was provided to participants in the “no extrinsic reward” condition. To ensure the effectiveness of the manipulation, a pre-test confirmed that the judges' evaluations and the monetary rewards were believable and were not seen to limit the way the designer performed the task. Once the experiment was complete, the three highest rated designs were then selected from the designs produced across all conditions, and the winners were notified and given their prize.

**Dependent Variable**

Two consumer judges from the target market (i.e., drivers over the age of 60) were recruited to evaluate the creativity of each product design (Dahl and Moreau 2002; Goldenberg, Mazursky, and Solomon 1999). Each judge received a booklet containing the 122 designs. The order of the designs was randomized across the booklets. The judges were blind to the identity of the participants, to one another, and to the purpose and conditions of the experiment. They were each paid $100 for their services.

Each judge completed an established six-item measure of the creativity of each design (see Moreau and Dahl 2005). Because creativity is commonly defined as the production of ideas considered both novel and useful (Burroughs, Moreau, and Mick 2008; Lubart 1994; Sternberg 1988), there were three items to capture each of the two dimensions (Moreau and Dahl 2005). The items (on a 7-point scale) were: not at all original/very original; not at all innovative/very innovative, not at all novel/very novel; not at all useful/very useful, not at all effective/very effective; not at all sensible/very sensible. Because we were interested in overall creativity, we
summed across all six items rather than keeping the novel and useful dimensions separate. This is in keeping with a considerable amount of prior research on creativity that argues both dimensions must be considered simultaneously, as one dimension without the other is not creative (see e.g., Lubart 1994; Smith, Ward, and Finke 1995; Plucker and Renzulli 1999). The combined approach has also been used in past marketing studies of creativity (Andrews and Smith 1996; Burroughs and Mick 2004; and Sethi, Smith, and Park 2001).

Following established procedures for assessing the validity of a measure involving multiple judges (Cicchetti 1994) we made a two-step assessment of our creativity scale. First, we calculated the coefficient alpha for each judge. Alpha estimates for the judges individually were high (α Judge A = .88, α Judge B = .79), so we next examined the level of agreement across judges by calculating the intra-class correlation coefficient (ICC). Using the ICC is appropriate for research involving multiple judges (compared to the Pearson product-moment correlation) because it accounts not only for the degree to which rater judgments covary (i.e. move up or down in unison) but also for the level of absolute agreement in the raters (i.e. high/high, medium/medium, low/low creativity; Cicchetti 1994). This is a more stringent test because it insures that independent evaluators are viewing the creativity of the design at approximately the same level. The intra-class correlation was also high (ICC = .86). Thus, we averaged across the judges’ ratings to create a composite score for the creativity of each design in the study (M = 3.8, range: 2.0 to 5.8) (Burroughs and Mick 2004; White and Smith 2001).

Results
Participants were told they would have up to an hour to complete the design task, though the research assistant did not stop them once they began working. The sessions were as short as seven minutes and as long as 119 minutes. The average session lasted 38 minutes.

In addition to the focal variables of interest in the research, several manipulation checks were included in the experiment. We assessed the effectiveness of the extrinsic reward manipulation by measuring the level of reward recall at the end of the study. We also assessed the effectiveness of the creativity training process. Two scale items assessed the extent to which participants visualized the customer and used images while developing their designs (1 = Did not visualize / use images of the customer, 7 = Visualized /used a lot of customer images). Further, in an open-response question, participants listed and described the customer images, if any, that they used during the design task. Two research assistants, blind to the purpose of the study, assessed each designer's list and description of their customer images, reporting the number of times the participant reported visualizing an elderly person using a jack. Agreement between the research assistants was high (ICC = .87), so their responses were averaged. Each of the three measures (2 self-report + 1 rated) was then standardized and summed to form an index of customer visualization (α = .96).

The awareness check for the reward manipulation showed that the procedure had made the award salient to participants as intended. Further, a two-way ANOVA revealed that, as intended, only the training manipulation significantly predicted the extent to which the participant visualized the consumer during the design task [M Training = .43 vs. M No Training = -.32; F(1, 121) = 4.67, p < .05]. Given this confirmation of our manipulations, we turned to examining their effect on our primary variable of interest, creativity.

A two-way ANOVA was used to assess the influence of the manipulations on design creativity. The results revealed a main effect of extrinsic rewards on creativity, with designs
created in conjunction with extrinsic rewards being rated as more creative than those produced in the absence of such incentives \[M_{\text{Reward}} = 4.03 \text{ vs. } M_{\text{No Reward}} = 3.66, F(1, 121) = 6.63, p < .01\].

However, as predicted, the influence of extrinsic rewards was contingent upon whether or not the participants had also received creativity training \[\text{interaction } F(1, 121) = 14.72, p < .001\]. Follow-up contrasts show that the designs created when both training and extrinsic rewards were provided were significantly more creative than those developed under any of the other three conditions in the experiment. In fact, in the absence of training, the provision of the reward actually causes creativity to go down slightly, albeit not significantly. Figure 1 provides a full depiction of the interaction and the relevant contrast statistics are as follows: \[M_{\text{Training, Reward}} = 4.35 \text{ vs. } M_{\text{No Training, Reward}} = 3.75, (F(1, 60) = 8.09, p < .01); M_{\text{Training, Reward}} = 4.35 \text{ vs. } M_{\text{Training, No Reward}} = 3.40, (F(1, 60) = 20.17, p < .001); M_{\text{Training, Reward}} = 4.35 \text{ vs. } M_{\text{No Training, No Reward}} = 3.93, (F(1, 60) = 3.87, p < .05)\].

Discussion

The results of this study demonstrate that by combining creativity training with an extrinsic reward, it is possible to enhance the creativity of the outcomes produced in a new product design task. In this study, creative idea production training was used to help participants to visualize the potential customer (an elderly person) engaged in the task (changing a flat tire). This type of training emphasizes concrete, problem-specific processing and task-relevant visualization. Again, the results show that this type of thinking, when combined with extrinsic rewards, enhanced the creativity of the designs produced.

However, our results do not tell us how these two managerial tools combined to enhance participants’ creativity. Neither the extrinsic reward nor the creativity training influenced the
amount of time spent on the creative task in this study. Thus, it is not a story of pure task persistence. Rather, the story appears to be more complex. In Study 3 we test the proposition that rewards and training will be mutually reinforcing to intrinsic motivation as an intermittent factor in the creative process. For those who receive creativity training, the rewards may encourage the people who are already working smarter to also work harder, and when they do so their intrinsic motivation may increase because they feel more competent in approaching the task. The next study is also designed to help generalize the findings to a different type of creativity training.

Study 3

Research Design

This study used a 2 x 2 between-participants experimental design, with the two manipulated factors being extrinsic rewards and creativity training. This time, however, training took the form of creative imagery training. Otherwise, to maintain continuity with the first experiment the conditions and procedures were the same. The new product context was again the design of a car jack for an elderly person. Study participants were engineering students (n=110) at a major west-coast university who received nominal compensation for their participation. Participants completed the study individually under the administration of a research assistant.

Independent Variables

Creative imagery training. Participants assigned the training manipulation again went through a creativity training session, only this time they were trained using Khatena’s (2000) divergent-symbolic production technique. Whereas participants in the first study went through a customer visualization exercise that was focused on the specific problem at hand, Khatena’s
program utilizes mental imagery in a more generalized way. Though the process is somewhat involved (see Khatena 2000, Chapter 8 for a fuller description), it essentially takes participants through a series of visualization steps. First, participants are asked to imagine that there is a box in a corner of the room. They are then asked to close their eyes and imagine what is inside the box. They write down as many of the objects they can recall thinking of and then group them together according to common properties. They are then instructed to once again close their eyes, visualize one of the object groupings, and imagine them coming to life. Specifically, participants must imagine the objects as characters in a play and write down their story. Though Khatena’s training programs were originally formulated to enhance the creativity of gifted children, they have been used widely in adult populations (Khatena 2000). The technique is designed to stimulate imaginative thinking and facilitate mental image production and manipulation.

Extrinsic rewards. As with the first experiment, half the participants in the study were told that their designs would be judged for creativity and that cash prizes of $250, $100, and $50 would be awarded to the top three designs. No such prize was offered to participants in the “no extrinsic reward” condition. Once the full experiment was complete, prize winners were selected from all experimental conditions, and the winners given their prize.

Dependent Variables

Creativity. Two consumer judges (different from those used in the first study but again over the age of 60) were utilized to judge the creativity of the car jack designs. Judges were each provided a booklet containing all of the designs along with a set of rating forms (containing the same creativity scale as Study 2). Judges were once again paid $100 for their services. When the judges completed their task, we again ascertained the internal consistency and level of inter-rater
agreement in the creativity ratings. Alpha for the scale for Judge A was .84, and for Judge B it was .78. The intra-class correlation coefficient between the judges was .87, indicating high agreement in their assessments (Cicchetti 1994). Thus, as with Study 2, the ratings were averaged across judges to form an overall creativity score (M = 3.6, range 1.0 to 5.6).

Intrinsic motivation. Because intrinsic motivation is at the center of the controversy over the effect of extrinsic rewards on creativity, this variable was included as a second dependent variable in the design. Intrinsic motivation can be ascertained at either a general level such as for a hobby or one’s work (Amabile et al. 1994) or for a specific task. Given our interest was in how the provision of a reward would influence creativity in a new product task, we focused on the latter form of intrinsic motivation. Unfortunately no measure of intrinsic motivation specific to new product design could be identified. Therefore we constructed a new measure guided by the literature (Amabile et al. 1994; Harackiewicz, Sansone, and Manderlink 1985; Shalley and Perry-Smith 2001). Recall that intrinsic motivation reflects inherent task interest (Amabile 1996; Csikszentmihalyi 1996), and is indicated by such things as the extent to which the individual finds the activity to be exciting, interesting, and challenging (Amabile 1996). It is also characterized by the extent to which an individual becomes engrossed in what they are doing, and finds the activity to be fulfilling (Csikszentmihalyi 1996). Using these as our guiding concepts, we constructed a five-item measure of task intrinsic motivation that study participants completed after doing the design task. Using a seven-point semantic differential format, this measure assessed the extent to which they found the new product design task to be: interesting, exciting, challenging, engrossing and fulfilling (versus uninteresting, boring, annoying, shallow, and unfulfilling). Factor analysis suggested the scale was unidimensional (all item loadings > .60; with a first factor accounting for 51% of the variance). Reliability for the scale was $\alpha = .75$. 
Results

To validate the extrinsic reward manipulation, designers again indicted their recall of the reward offered at the conclusion of the study. The creativity training manipulation was validated by ensuring that the designer completed Khatena’s divergent symbolic production task as a first step in the experimental process and all of the participants met these criteria respective to their condition. Given this we turned to analyzing the effects of our independent variables on design creativity.

Creativity. ANOVA was used to test the effects of extrinsic rewards, creativity training, and their interaction on the creativity of the product designs. Training exhibited no main effect influence on creativity while extrinsic rewards exhibited a significant positive influence as it had in Study 2 ($F(1, 106) = 5.50, p < .02$). However, like Study 2, this main effect is qualified by a significant interaction between the two independent factors ($F(1, 106) = 5.01, p < .03$). As shown in Figure 2, when no training was provided, extrinsic rewards did nothing to improve the creativity of the outcomes produced. However, among participants who received training, the story is markedly different. Here, as in the prior study, there is a pronounced increase in the creativity of the designs among those who received an external reward compared to their unrewarded counterparts [contrast: $M_{\text{Training, Reward}} = 4.03$ vs. $M_{\text{Training, No Reward}} = 3.27$, $F(1, 54) = 10.13, p < .002$]. Moreover, participants who received training along with an extrinsic reward exhibited significantly higher levels of creativity than in any of the other conditions of the study [contrasts: $M_{\text{Training, Reward}} = 4.03$ vs. $M_{\text{No Training, Reward}} = 3.57$, $F(1, 54) = 4.92, p < .03$; $M_{\text{Training, Reward}} = 4.03$ vs. $M_{\text{No Training, No Reward}} = 3.55$, $F(1, 55) = 4.89, p < .03$].

---- Insert Figure 2 about here ----
Intrinsic motivation. This study was also designed to examine the role of intrinsic motivation in the creative process. To investigate this variable we performed the following analyses. First, we ran the same two-way ANOVA as for our creativity measure, substituting intrinsic motivation as the dependent variable. The results support an important role for intrinsic motivation and reveal a significant interaction \[ F(3, 104) = 7.20, p < .01 \]. Among participants who were untrained, the provision of an extrinsic reward had a negligible effect on intrinsic motivation \[ \text{M No Training, No Reward} = 3.92 \text{ vs. M No Training, Reward} = 3.91, F(1, 53) = 0.01, p = ns \]. Though not the significant decline in intrinsic motivation that has been previously reported in the creativity literature, it does little to refute this position. More importantly, for participants who received creativity training the results are quite different. Now the provision of an extrinsic reward produces a pronounced increase in intrinsic motivation \[ \text{M Training, No Reward} = 3.66 \text{ vs. M Training, Reward} = 4.34, F(1, 51) = 21.49, p < .001 \]. In fact, training and rewards in combination produced the highest levels of intrinsic motivation in the study by a significant margin \[ \text{contrasts: M Training, Reward} = 4.34 \text{ vs. M No Training, Reward} = 3.91, F(1, 53) = 6.03, p < .02; \text{M Training, Reward} = 4.34 \text{ vs. M No Training, No Reward} = 3.92, F(1, 54) = 5.93, p < .02 \].

Clearly the provision of an external reward is accepted and interpreted quite differently among participants who had first received creativity training than among those who had received no such training. This finding affirms the important role of intrinsic motivation in the creative process but, contrary to the prevailing view that extrinsic rewards necessarily undermine intrinsic motivation, our results show that extrinsic rewards can actually increase intrinsic motivation in certain conditions (i.e. when individuals are also given proper training).

It is worth noting the similarity of the pattern of effects between intrinsic motivation and the creativity of the new product designs. The patterns are highly consistent despite the fact that
one measure (intrinsic motivation) came from self-reports of the participants themselves while
the other (creativity) came from independent judges blind to conditions of the study. This
separation makes it unlikely that the findings are due to common method variance or some other
study artifact.

**Mediation analysis.** The prior analysis examined intrinsic motivation separately from
creative outcomes. However we were also hoping to show evidence that these constructs are
linked through the creative process. In other words we were interested in investigating the set of
mediated relationships within the context of the creativity training moderator. Therefore we also
conducted a multiple group analysis. This analysis involves splitting our study participants into
two groups (training/no training) and then using structural equation modeling to compare the
paths of extrinsic rewards to intrinsic motivation to creative outcomes between the two groups
(Edwards and Lambert 2007). To avoid problems created by a high item-to-sample ratio, we first
created composite indicants of our measures through a partial disaggregation CFA model
(Bagozzi and Heatherton 1994). The principal advantage of this technique is it reduces the
number of parameters to be estimated in the model and helps reduce measurement error.

When this analysis is undertaken an interesting set of relationships emerge. Extrinsic
rewards are positively related to intrinsic motivation which is, in turn, positively linked to
creative product outcomes, but only for participants who had first completed the creativity
training regimen [extrinsic reward— intrinsic motivation ($\beta = 1.05$, $t = 4.54$, critical $t = 1.96$);
intrinsic motivation— creative outcomes ($\beta = .47$, $t = 2.17$, critical $t = 1.96$)]. Among our
untrained participants there is no relationship between extrinsic rewards, intrinsic motivation, or
creative outcomes [extrinsic reward— intrinsic motivation ($\beta = -.02$, $t = -.06$, critical $t = 1.96$);
intrinsic motivation— creative outcomes ($\beta = -.02$, $t = -.12$, critical $t = 1.96$); overall model fit
This additional analysis further supports our contention that extrinsic rewards can enhance creative product outcomes, but only when they are used in conjunction with appropriate training. It also supports the notion that this process flows through intrinsic motivation. It appears that the combination of training and rewards enables designers to work both smarter and harder. This is, to our knowledge, the first time creativity training, extrinsic rewards, intrinsic motivation, and creative product outcomes have all been simultaneously linked.

**Discussion**

In two experiments we find that creativity training interacts with extrinsic rewards to enhance the creativity of new product outcomes. Importantly, this synergy exists whether the training is in the form of focused ideation production or the more generalized creative imagery technique. However, the consistency of these findings raises the obvious question of whether any visualization might be sufficient to produce this outcome (why go to the trouble of elaborate training regimens if one can just have someone “imagine anything”). While the training techniques we employed in our studies have been developed and refined over many years this is a legitimate question, particularly given our control condition did not involve visualization.

To address this concern, we undertook a follow-up study using newly recruited participants. In this study, we used the same training procedures, same design task, and same judges as Study 2. Because this study is focused on the nature of the training manipulation, we blocked on reward condition (i.e. the reward was offered to all study participants). Otherwise participants were randomly assigned to either the new control condition or the creativity training condition. In the new control condition, instead of “doing nothing,” participants completed a statistics: Chi-Sq 56.37, CFI = .93; NNFI = .90; RMSEA = .09).
guided visualization task that involved the peeling and eating of a lemon. This task was sourced from a website that provides exercises to familiarize individuals with visualization techniques. The control condition and the training condition were parallel in time taken to complete. Participants who received creative visualization training exhibited significantly higher creativity in their product designs than did individuals who participated in a random visualization task [M Creative Visualization = 4.10, M Control Visualization = 3.66, t(37) = 1.96, p < .05, n=39]. Thus, although there appears to be some flexibility in how the visualization training is accomplished, it must be creativity directed. Any random visualization task is not sufficient to produce creative outcomes.

General Discussion

Few issues are more important to the long-term success of a firm than the development of innovative new products. Thus, understanding the conditions and processes that lead to such innovations has long been a focus of marketing research. Within this domain, scholarship has investigated the firm competencies and capabilities that lead to product innovation (Chandy et al. 2006; Im and Workman 2004; Sethi 2000; Troy, Hirunyawipada and Paswan 2008), the role of inter-firm relationships and strategic alliances in bringing new product innovations to market (Carson 2007; Ganesan, Malter and Rindfleisch 2005), cross-cultural influences on the new product development process (Nakata and Sivakumar 1996; Song and Parry 1997; Tellis, Prabhu and Chandy 2009), and the role of consumers in new product innovation and diffusion (Bendapudi and Leone 2003; Fang 2008; Hoeffler 2003; Joshi and Sharma 2004; Wood and Moreau 2006). Unfortunately, while creativity is relevant in all of these conversations, few of these studies actively consider its role in their investigations. Perhaps this neglect stems from the widespread perception of creativity as something “mystical” or “divinely imparted,” as opposed
to a normal cognitive process that can be enhanced (Sternberg and Lubart 1999; Weisburg 1993).

As one of our informants explained,

"One of the reasons I think creativity is not consciously addressed and talked about in business is because of people's misunderstanding of creativity. I think many see creativity as a separate segment of the population, a separate skill set. Many high-performing CEOs and leaders are probably very creative, but most people label them as ‘intellectually brilliant’ or having ‘good organizational skills.’ By not including creativity in that vocabulary, in that script, it becomes undervalued."

Our research helps refute this misconception by demonstrating that creativity can be facilitated through two tools commonly at a manager’s disposal: incentives and training.

**Managerial Implications**

One practical implication of our findings is that firms should do more to provide creativity training to employees. Although such a recommendation may appear rather obvious in hindsight, a notable number of the firms in our study do not provide any type of formal creativity training for their employees (even for personnel working in key areas such as new product design). The entirety of these firms’ creative strategy entails hiring the right people then simply expecting they will be creative. Our results show that even relatively simple creative visualization exercises can pay substantial dividends when it comes to enhancing creative outcomes.

Of course, training may be for naught if it is not paired with the proper incentives, and this may be the most important insight to emerge from our research. As our findings make clear, rewards and training cannot be viewed independent of one another. Yet all too often managers treat these as separate issues, particularly in the case of rewards. While we now have convincing evidence that trying to use extrinsic rewards to induce creativity is more likely to produce the
opposite effect (see e.g., Amabile 1996; Deci, Koestner, and Ryan 1999a), managers appear either unaware or unwilling to heed this evidence. A common recommendation in the management literature therefore, is to find ways to reduce reliance on rewards (Amabile 1998). However, our results suggest this advice may be premature. Although we acknowledge that when extrinsic rewards are offered in isolation they are likely to be counterproductive, the same cannot be said when rewards are offered in conjunction with appropriate training. Offering training along with a reward stands to benefit individuals in two ways. Not only does the training enhance capabilities, it also shifts interpretation of the reward from some type of an enticement, to an affirmation of valued contribution. In short, when empowered by training, the addition of the reward raises intrinsic motivation for challenging tasks.

Our findings highlight the complexities inherent in managing creativity, but also the potential to leverage creativity through the careful application of common managerial tools like incentives and training. While we consider the current results to be encouraging, additional contextual factors are likely to further moderate the effectiveness of these tools, and therefore represent opportunities for future research.

**Limitations and Future Research**

It is important to acknowledge the limitations to this research, all of which present opportunities for further investigation. Our experimental methodology has some limits in terms of external validity. We were limited in the amount of training we were able to give our research participants. While past research has shown that even limited creativity training can be quite beneficial (Clapham 1997; Dahl, Chattopadhyay, and Gorn 1999), more extensive training would
obviously be desirable, particularly in real industry settings. Thus, we consider our findings to represent a rather conservative test of the benefit of combining training and reward programs.

We also chose an extrinsic reward that provided a financial incentive for the designs judged as “best.” Firms make use of a wide variety of extrinsic incentives including bonuses, contests, promotions, and even punitive threats to try and increase productivity. These incentives may operate in different ways, especially in their interaction with training. For example, the extrinsic reward we used (a contest) likely induces competition among the designers to secure the prize. Future research has an opportunity to disentangle financial and competitive incentives to better understand how the effectiveness of training can be enhanced.

Our experiments were also limited to a single design problem in an effort to control extraneous influences across the studies. While we believe that an improved car jack for the elderly represents a very realistic and natural type of problem new product designers are likely to encounter, it is nonetheless a specific type of problem. It would be interesting to see if our results hold for other types of NPD contexts, particularly in high technology areas like microchips, software development, and aerospace engineering.

Additionally, our research focused primarily on individual-level aspects of creativity (e.g. cognitive processes, internal motivations). However, in industry these factors will often transpire within a group context, such as part of a cross-functional team (e.g. Sethi 2000; Troy, Hirunyawipada, and Paswan 2008; Rathnam, Mahajan, and Whinston 1995). This provides an opportunity to expand into new research questions: Do individual motivations change when they are embedded in a group context? Does rewarding team performance alter the creative equation compared to rewarding individual initiative? How might team dynamics enhance (or attenuate)
the benefits of training? The lack of answers to questions such as these highlights the need for future research to examine the role of creativity at multiple levels.

Another opportunity exists to extend research into the question of outside expertise. A number of the firms in our qualitative study outsourced a significant portion of the creative task to consultants. This raises the question, if intrinsic motivation is so fundamental to this process, why do firms so readily to pay someone else to produce creative ideas? Would a consultant have the same intrinsic motivation that an employee would? The simple answer would be no (their effort is supplied in direct exchange for compensation). On the other hand, presumably consultants work in creative fields because they really enjoy it, and so may enter the process with high levels of intrinsic motivation to begin with. There has been very little research that considers the influence of agent relationships such as consultants on creativity, which is again surprising given how prevalent this practice is in industry.

Finally, our participants were engineering students who were at the beginning of their careers, and so their receptiveness to training and natural intrinsic motivation would both likely be high. Again, the fact we still found differences actually suggests robustness in our results. Nonetheless, it would be interesting to examine whether our results would replicate using a group of mid-career engineers or more senior designers. The past successes and failures of these individuals is likely to influence both their receptiveness to training, and their interpretation of incentive programs. Thus, while our studies provide a good starting point, there are many ways subsequent studies could branch out, in terms of identifying further limitations and boundary conditions of this interaction.

Visualization Training

In solving design problems, many designers find that forming visual images (pictures in the mind) can help them produce innovative and effective designs. One visualization strategy that has been shown to aid in the design process involves visualizing the potential customer of the product. Seeing in your mind, a product-user being involved and interacting with a proposed product design can facilitate the development of design solutions.

For many individuals, visualizing the customer is a difficult task. The present training task is a guided imagery exercise that provides practice in visualizing the customer. Please read through the following paragraph and attempt to visualize the images expressed. After reading each sentence, close your eyes and visually process the expressed ideas and try to "see" the customer in the product usage situation.

Please picture in your mind a young adult. Perhaps someone that is in their early twenties. Imagine that the young adult is quite thin and petite. In your mind you can see them in their apartment. The apartment is quite small having only a bedroom, kitchen, living room, and a bathroom. Imagine the young adult coming into their living room. You see that they are dragging a large box. The box is obviously very heavy for the young adult and the size of it is almost overwhelming. You watch as they struggle to move the box into the centre of the room. After quite some time they finish positioning the box and begin to open it. The thick packaging tape makes opening a difficult task. You can see the young adult getting frustrated and in anger they attempt to rip at the cardboard. Finally the box is open. You see that in the box are the pieces to a set of new wooden tv dinner stands. Dumping the contents on the living room floor, the young adult searches for the page of instructions. The instruction sheet is on a small piece of cardboard and you can tell that the printing on the sheet is quite small. You can tell that the young adult is having trouble reading the fine print of the instructions. You watch as the young adult reaches to a nearby shelf and opens a glasses case, retrieves a pair of glasses, and then puts them on. The young adult studies the instruction sheet for what seems like an eternity. Finally, they put down the instructions and they begin to assemble the stand. You can tell that they are confused by the instructions and the many differing types of screws, pieces of wood, and other assembly materials. You watch as the young adult picks up the largest piece of wood from the floor. You can tell that their small hands are obviously not large enough to hold the wood, and you watch as the heavy piece slips from their hand and crashes to the floor. Leaving this scene you wonder if the new stand will ever be assembled.

After completing the visualization exercise please raise your hand and the experimenter will give you the design task. In the design task you will be asked to image a customer using a proposed product design. We suggest that you adopt a visualization process similar to that learned in this
training session. Imaging a scenario that identifies the specific characteristics of the customer as he or she interacts with the proposed design will facilitate your ability to produce an effective and innovative design.

Design Task

You are asked to develop an innovative and effective car jack design for elderly adults (age 60+). Please produce a thumbnail sketch of your design and include any brief written comments that are necessary to explain your design. Please disregard any economic, material, or regulatory constraints as you develop your idea. You have up to one hour to complete your design. As indicated by the experimenter, please use the scrap paper for your initial sketching, and the bonded paper for your final design.
